13 Jürgen Drewe <juergendrewe@zellerag.ch>

14 Random forest, support vector machine, logistic regression, neural net-  
15 works and k-nearest neighbor (**lazar**) algorithms, were applied to a new  
16 *Salmonella* mutagenicity dataset with 8290 unique chemical structures utiliz-  
17 ing MolPrint2D and Chemistry Development Kit (CDK) descriptors. Cross-  
18 validation accuracies of all investigated models ranged from 80-85% which  
19 is comparable with the interlaboratory variability of the *Salmonella* muta-  
20 genicity assay. Pyrrolizidine alkaloid predictions showed a clear distinction  
21 between chemical groups, where otonecines had the highest proportion of  
22 positive mutagenicity predictions and monoesters the lowest.

## 23 Introduction

24 The assessment of mutagenicity is an important part in the safety assessment of chemical  
25 structures, because mutations may lead to cancer and germ cells damage. The bacterial  
26 reverse mutation test (Ames test) is capable to identify substances that cause mutations  
27 (e.g., base-pair substitutions, frameshifts, insertions, deletions) and is generally used as  
28 the first step in genotoxicity and carcinogenicity assessments.

29 Computer based (*in silico*) mutagenicity predictions can be used in the early screening of  
30 novel compounds (e.g. drug candidates), but they are also gaining regulatory acceptance  
31 e.g. for the registration of industrial chemicals within REACH (European Chemicals  
32 Agency (ECHA) (2017)) or the assessment of impurities in pharmaceuticals (ICH M7  
33 guideline, Harmonisation of Technical Requirements for Pharmaceuticals for Human Use  
34 International Council for Harmonisation of Technical Requirements for Pharmaceuticals  
35 for Human Use (ICH) (2017)).

36 Currently, mutagenicity is the toxicological endpoint with the largest amount of public  
37 data for almost 10000 structures, whereas datasets for other endpoints contain typically  
38 only a few hundred compounds. The Ames test itself is relatively reproducible with an  
39 interlaboratory variability of 80-85% (Piegorsch and Zeiger (1991)).

40 This makes the development of mutagenicity models also interesting from a computa-  
41 tional chemistry and machine learning point of view. The relatively large amount of  
42 public data reduces the probability of chance effects due to small sample sizes and the  
43 reliability of the underlying assay reduces the risk of overfitting experimental errors.

44 Within this study we attempted

- 45 • to generate a new public mutagenicity training dataset focusing on *Salmonella*  
46 *typhimurium*, by combining the most comprehensive public datasets
- 47 • to compare the performance of MolPrint2D (*MP2D*) fingerprints with Chemistry

48 Development Kit (*CDK*) descriptors for mutagenicity predictions  
49 • to compare the performance of global QSAR models (random forests (*RF*), support  
50 vector machines (*SVM*), logistic regression (*LR*), neural nets (*NN*)) with local  
51 models (*lazar*)

52 To demonstrate the application of mutagenicity models to compounds with very limited  
53 experimental data and to show their strengths and weaknesses we decided to apply them  
54 to Pyrrolizidine alkaloids (PAs).

55 Pyrrolizidine alkaloids (PAs) are characteristic metabolites of some plant families,  
56 mainly: *Asteraceae*, *Boraginaceae*, *Fabaceae* and *Orchidaceae* (Hartmann and Witte  
57 (1995), Langel, Ober, and Pelser (2011)) and form a powerful defence mechanism  
58 against herbivores. PAs are heterocyclic ester alkaloids composed of a necine base (two  
59 fused five-membered rings joined by a single nitrogen atom) and a necic acid (one or  
60 two carboxylic ester arms), occurring principally in two forms, tertiary base PAs and  
61 PA N-oxides.

62 In mammals, PAs are mainly metabolized in the liver. There are three principal  
63 metabolic pathways for 1,2-unsaturated PAs (Chen, Mei, and Fu (2010)):

- 64 • Detoxification by hydrolysis of the ester bond on positions C7 and C9 by non-  
65 specific esterases to release necine base and necic acid.
- 66 • N-oxidation of the necine base to form PA N-oxides, which can be either conjugated  
67 by phase II enzymes and then excreted or converted back into the corresponding  
68 parent PA (Wang et al. (2005)). This detoxification pathway is not possible for  
69 otonecine-type PAs, as they are N-methylated (see Figure 1).
- 70 • Metabolic activation or toxification by oxidation (for retronecine-type PAs) or  
71 oxidative N-demethylation (for otonecine-type PAs) by cytochromes P450 isoforms  
72 CYP2B and 3A (Lin, Cui, and Hawes (1998), Ruan et al. (2014)).

73 The latter reactions result in the formation of dehydropyrrolizidine (DHP) that is highly  
74 reactive and causes damage by building adducts with protein, lipids and DNA (Chen,  
75 Mei, and Fu (2010)). On the other hand, open diesters and macrocyclic PAs have a  
76 reduced detoxification due to steric hinderance of the respective esterases (Ruan et al.  
77 (2014)).

78 Therefore, the mutagenic probability of PAs is highly dependent on the structure of  
79 necine base and necic acid (Hadi et al. (2021); Allemang et al. (2018), Louisse et al.  
80 (2019)). However, due to limited availability of pure substances, only a small number of  
81 PAs have been investigated experimentally in an Ames test. To overcome this bottleneck,  
82 the application of different machine learning models to predict mutagenic probabilities  
83 based on structures and properties could provide further insights into the mutagenicity  
84 mechanisms of PAs.

## 85 **Materials and Methods**

### 86 **Data**

#### 87 **Mutagenicity training data**

88 An identical training dataset was used for all models. The training dataset was compiled  
89 from the following sources:

- 90 • Kazius/Bursi Dataset (4337 compounds, Kazius, McGuire, and Bursi (2005)):  
91 [http://cheminformatics.org/datasets/bursi/cas\\_4337.zip](http://cheminformatics.org/datasets/bursi/cas_4337.zip)
- 92 • Hansen Dataset (6513 compounds, Hansen et al. (2009)): [http://doc.ml.tu-berlin.  
93 de/toxbenchmark/Mutagenicity\\_N6512.csv](http://doc.ml.tu-berlin.de/toxbenchmark/Mutagenicity_N6512.csv)
- 94 • EFSA Dataset (695 compounds EFSA (2016)): [https://data.europa.eu/euodp/  
95 data/storage/f/2017-0719T142131/GENOTOX%20data%20and%20dictionary.xls](https://data.europa.eu/euodp/data/storage/f/2017-0719T142131/GENOTOX%20data%20and%20dictionary.xls)

96 Mutagenicity classifications from Kazius and Hansen datasets were used without further  
97 processing. According to these publications, compounds were classified as mutagenic if  
98 at least one positive result has been obtained in *Salmonella typhimurium* strains TA97,  
99 TA98, TA100, TA102, TA1535, TA1537 and TA1538 either with or without metabolic  
100 activation by S9. *E. coli* results were not considered in these databases. To achieve  
101 consistency with these datasets, EFSA compounds were classified as mutagenic, if at  
102 least one positive result was found for the same *Salmonella* strains either with or without  
103 metabolic activation and as non-mutagenic if no positive result was found. The complete  
104 dataset contains chemicals from very diverse application areas (e.g. pharmaceuticals,  
105 pesticides, industrial chemicals, environmental contaminants).

106 Dataset merges were based on unique SMILES (*Simplified Molecular Input Line En-*  
107 *try Specification*, Weininger, Weininger, and Weininger (1989)) strings of the compound  
108 structures. Duplicated experimental data with the same outcome was merged into a  
109 single value, because it is likely that it originated from the same experiment. Contradic-  
110 tory results were kept as multiple measurements in the database. The combined training  
111 dataset contains 8290 unique structures and 8309 individual measurements. Contradic-  
112 tory results were found for 19 substances.

113 Source code for all data download, extraction and merge operations is pub-  
114 licly available from the git repository <https://git.in-silico.ch/mutagenicity-paper>  
115 under a GPL3 License. The new combined dataset can be found at <https://git.in-silico.ch/mutagenicity-paper/tree/mutagenicity/mutagenicity.csv>.

### 117 **Pyrrolizidine alkaloid (PA) dataset**

118 The pyrrolizidine alkaloid dataset was created from five independent, necine base sub-  
119 structure searches in PubChem (<https://pubchem.ncbi.nlm.nih.gov/>) and compared to  
120 the PAs listed in EFSA (2011) and the book by Mattocks (1986), to ensure, that all

Figure 1: Structural features of pyrrolizidine alkaloids

121 major PAs were included. PAs mentioned in these publications, which were not found  
 122 in the downloaded substances were searched individually in PubChem and, if available,  
 123 downloaded separately. Non-PA substances, duplicates, and isomers were removed from  
 124 the files, but artificial PAs, even if unlikely to occur in nature, were kept. The resulting  
 125 PA dataset comprised a total of 602 different PAs. Further details about the compilation  
 126 of the PA dataset are described in Schöning et al. (2017).

127 The PAs in the dataset were classified according to structural features. A total of 9  
 128 different structural features were assigned to the necine base, to modifications of the  
 129 necine base and to the necic acid (Figure 1):

130 For the necine base, the following structural features were chosen:

- 131 • Retronecine-type (1,2-unsaturated necine base, 392 compounds)
- 132 • Otonecine-type (1,2-unsaturated necine base, 46 compounds)
- 133 • Platynecine-type (1,2-saturated necine base, 140 compounds)

134 For the modifications of the necine base, the following structural features were chosen:

- 135 • N-oxide-type (84 compounds)
- 136 • Dehydropyrrolizidine-type (DHP, pyrrolic ester, 23 compounds)
- 137 • Tertiary-type (PAs which were neither from the N-oxide- nor DHP-type, 495 com-  
138 pounds)

139 For the necic acid, the following structural features were chosen:

- 140 • Monoester-type (154 compounds)
- 141 • Open-ring diester-type (163 compounds)
- 142 • Macrocyclic diester-type (255 compounds)

## 143 **Descriptors**

### 144 **MolPrint2D (MP2D) fingerprints**

145 MolPrint2D fingerprints (O’Boyle et al. (2011)) use atom environments as molecular  
146 representation. They determine for each atom in a molecule, the atom types of its  
147 connected atoms to represent their chemical environment. This resembles basically the  
148 chemical concept of functional groups.

149 In contrast to predefined lists of fragments (e.g. FP3, FP4 or MACCs fingerprints) or  
150 descriptors (e.g CDK) they are generated dynamically from chemical structures. This  
151 has the advantage that they can capture unknown substructures of toxicological relevance  
152 that are not included in other descriptors. In addition, they allow the efficient calculation  
153 of chemical similarities (e.g. Tanimoto indices) with simple set operations.

154 MolPrint2D fingerprints were calculated with the OpenBabel cheminformatics library  
155 (O’Boyle et al. (2011)) for the complete training dataset with 8290 unique structures.  
156 They can be obtained from the following locations:

157 *Training data:*

- 158 • sparse representation (<https://git.in-silico.ch/mutagenicity-paper/tree/mutagenicity/mutagenicity-mp2d>)
- 160 • descriptor matrix (<https://git.in-silico.ch/mutagenicity-paper/tree/mutagenicity/mutagenicity-mp2d.csv.gz>)

162 *Pyrrolizidine alkaloids:*

- 163 • sparse representation (<https://git.in-silico.ch/mutagenicity-paper/tree/pyrrolizidine-alkaloids/pa-mp2d>)
- 165 • descriptor matrix (<https://git.in-silico.ch/mutagenicity-paper/tree/pyrrolizidine-alkaloids/pa-mp2d.csv>)

### 167 **Chemistry Development Kit (CDK) descriptors**

168 Molecular 1D and 2D descriptors were calculated with the PaDEL-Descriptors program  
169 (<http://www.yapcsoft.com> version 2.21, Yap (2011)). PaDEL uses the Chemistry De-  
170 velopment Kit (CDK, <https://cdk.github.io/index.html>) library for descriptor calcula-  
171 tions.

172 As the training dataset contained 8309 instances, it was decided to delete all instances  
173 where CDK descriptor calculations failed during pre-processing. Furthermore, 19 sub-  
174 stances with contradictory experimental results were removed. The final training dataset  
175 contained 1442 descriptors for 8083 compounds.

176 CDK training data can be obtained from <https://git.in-silico.ch/mutagenicity-paper/tree/mutagenicity/mutagenicity-cdk.csv>.

178 The same procedure was applied for the pyrrolizidine dataset yielding descriptors for  
179 compounds. CDK features for pyrrolizidine alkaloids are available at <https://git.in-silico.ch/mutagenicity-paper/tree/pyrrolizidine-alkaloids/pa-cdk.csv>.

## 181 Algorithms

### 182 **lazar**

183 **lazar** (*lazy structure activity relationships*) is a modular framework for read-across model  
184 development and validation. It follows the following basic workflow: For a given chemical  
185 structure **lazar**:

- 186 • searches in a database for similar structures (neighbours) with experimental data,
- 187 • builds a local QSAR model with these neighbours and
- 188 • uses this model to predict the unknown activity of the query compound.

189 This procedure resembles an automated version of read across predictions in toxicology.  
190 In machine learning terms it would be classified as a k-nearest-neighbour algorithm.

191 Apart from this basic workflow, **lazar** is completely modular and allows the researcher to  
192 use arbitrary algorithms for similarity searches and local QSAR (*Quantitative structure–*  
193 *activity relationship*) modelling. Algorithms used within this study are described in the  
194 following sections.

### 195 **Feature preprocessing**

196 MolPrint2D features were used without preprocessing. Near zero variance and strongly  
197 correlated CDK descriptors were removed and the remaining descriptor values were  
198 centered and scaled. Preprocessing was performed with the R **caret** `preProcess` function  
199 using the methods “nzv”, “corr”, “center” and “scale” with default settings.

### 200 **Neighbour identification**

201 Utilizing this modularity, similarity calculations were based both on MolPrint2D finger-  
202 prints and on CDK descriptors.

203 For MolPrint2D fingerprints chemical similarity between two compounds  $a$  and  $b$  is  
204 expressed as the proportion between atom environments common in both structures  
205  $A \cap B$  and the total number of atom environments  $A \cup B$  (Jaccard/Tanimoto index).

$$sim = \frac{|A \cap B|}{|A \cup B|}$$

206 For CDK descriptors chemical similarity between two compounds  $a$  and  $b$  is expressed  
207 as the cosine similarity between the descriptor vectors  $A$  for  $a$  and  $B$  for  $b$ .

$$sim = \frac{A \cdot B}{|A||B|}$$

208 Threshold selection is a trade-off between prediction accuracy (high threshold) and the  
209 number of predictable compounds (low threshold). As it is in many practical cases  
210 desirable to make predictions even in the absence of closely related neighbours, we follow  
211 a tiered approach:

- 212 • First a similarity threshold of 0.5 (MP2D/Tanimoto) or 0.9 (CDK/Cosine) is used  
213 to collect neighbours, to create a local QSAR model and to make a prediction for  
214 the query compound. This are predictions with *high confidence*.
- 215 • If any of these steps fails, the procedure is repeated with a similarity threshold of  
216 0.2 (MP2D/Tanimoto) or 0.7 (CDK/Cosine) and the prediction is flagged with a  
217 warning that it might be out of the applicability domain of the training data (*low*  
218 *confidence*).
- 219 • These similarity thresholds are the default values chosen by software developers  
220 and remained unchanged during the course of these experiments.

221 Compounds with the same structure as the query structure are automatically eliminated  
222 from neighbours to obtain unbiased predictions in the presence of duplicates.

## 223 Local QSAR models and predictions

224 Only similar compounds (neighbours) above the threshold are used for local QSAR  
225 models. In this investigation, we are using a weighted majority vote from the neigh-  
226 bour’s experimental data for mutagenicity classifications. Probabilities for both classes  
227 (mutagenic/non-mutagenic) are calculated according to the following formula and the  
228 class with the higher probability is used as prediction outcome.

$$p_c = \frac{\sum \text{sim}_{n,c}}{\sum \text{sim}_n}$$

229  $p_c$  Probability of class c (e.g. mutagenic or non-mutagenic)

230  $\sum \text{sim}_{n,c}$  Sum of similarities of neighbours with class c

231  $\sum \text{sim}_n$  Sum of all neighbours

## 232 Applicability domain

233 The applicability domain (AD) of **lazar** models is determined by the structural diver-  
234 sity of the training data. If no similar compounds are found in the training data no  
235 predictions will be generated. Warnings are issued if the similarity threshold had to be  
236 lowered from 0.5 to 0.2 in order to enable predictions. Predictions without warnings  
237 can be considered as close to the applicability domain (*high confidence*) and predictions  
238 with warnings as more distant from the applicability domain (*low confidence*). Quantita-  
239 tive applicability domain information can be obtained from the similarities of individual  
240 neighbours.

## 241 Validation

242 10-fold cross validation was performed for model evaluation.

## 243 **Pyrrolizidine alkaloid predictions**

244 For the prediction of pyrrolizidine alkaloids models were generated with the MP2D and  
245 CDK training datasets. The complete feature set was used for MP2D predictions, for  
246 CDK predictions the intersection between training and pyrrolizidine alkaloid features  
247 was used.

## 248 **Availability**

## 256 **Tensorflow models**

### 257 **Feature Preprocessing**

258 For preprocessing of the CDK features we used a quantile transformation to a uniform  
259 distribution. MP2D features were not preprocessed.

### 260 **Random forests (*RF*)**

261 For the random forest classifier we used the parameters `n_estimators=1000` and  
262 `max_leaf_nodes=200`. For the other parameters we used the scikit-learn default values.

263 **Logistic regression (SGD) (*LR-sgd*)**

264 For the logistic regression we used a combination of five trained models. For each model  
265 we used a batch size of 64 and trained for 50 epochs. As an optimizer ADAM was chosen.  
266 For the other parameters we used the tensorflow default values.

267 **Logistic regression (scikit) (*LR-scikit*)**

268 For the logistic regression we used as parameters the scikit-learn default values.

269 **Neural Nets (*NN*)**

270 For the neural network we used a combination of five trained models. For each model we  
271 used a batch size of 64 and trained for 50 epochs. As an optimizer ADAM was chosen.  
272 The neural network had 4 hidden layers with 64 nodes each and a ReLu activation  
273 function. For the other parameters we used the tensorflow default values.

274 **Support vector machines (*SVM*)**

275 We used the SVM implemented in scikit-learn. We used the parameters kernel='rbf',  
276 gamma='scale'. For the other parameters we used the scikit-learn default values.

277 **Validation**

278 10-fold cross-validation was used for all Tensorflow models.

279 **Pyrrolizidine alkaloid predictions**

280 For the prediction of pyrrolizidine alkaloids we trained the model described above on  
281 the training data. For training and prediction only the features were used that were in  
282 the intersection of features from the training data and the pyrrolizidine alkaloids.

## 283 Availability

284 Jupyter notebooks for these experiments can be found at the following locations

285 *Crossvalidation:*

- 286 • MolPrint2D fingerprints: <https://git.in-silico.ch/mutagenicity-paper/tree/crossvalidations/tensorflow/prediction-v5-norm.ipynb>
- 287
- 288 • CDK descriptors: <https://git.in-silico.ch/mutagenicity-paper/tree/crossvalidations/tensorflow/prediction-v5-ext.ipynb>
- 289

290 *Pyrrrolizidine alkaloids:*

- 291 • MolPrint2D fingerprints: <https://git.in-silico.ch/mutagenicity-paper/tree/pyrrolizidine-alkaloids/tensorflow/prediction-v5-ext-ext-Padel-2D.ipynb>
- 292
- 293 • CDK descriptors: <https://git.in-silico.ch/mutagenicity-paper/tree/pyrrolizidine-alkaloids/tensorflow/prediction-v5-ext-Padel-2D.ipynb>
- 294

## 295 Results

### 296 10-fold crossvalidations

297 Crossvalidation results are summarized in the following tables: Table 1 shows results  
298 with MolPrint2D descriptors and Table 2 with CDK descriptors.

Table 1: Summary of crossvalidation results with MolPrint2D descriptors (lazar-HC: lazar with high confidence, lazar-all: all lazar predictions, RF: random forests, LR-sgd: logistic regression (stochastic gradient descent), LR-scikit: logistic regression (scikit), NN: neural networks, SVM: support vector machines)

	lazar-HC	lazar-all	RF	LR-sgd	LR-scikit	NN	SVM
Accuracy	84	82	80	84	84	84	84
True positive rate	89	85	78	83	83	82	83

	lazar-HC	lazar-all	RF	LR-sgd	LR-scikit	NN	SVM
True negative rate	78	78	82	84	85	85	86
Positive predictive value	83	80	81	84	84	84	85
Negative predictive value	86	84	80	84	84	83	84
Nr. predictions	5864	7782	8303	8303	8303	8303	8303

Table 2: Summary of crossvalidation results with CDK descriptors (lazar-HC: lazar with high confidence, lazar-all: all lazar predictions, RF: random forests, LR-sgd: logistic regression (stochastic gradient descent), LR-scikit: logistic regression (scikit), NN: neural networks, SVM: support vector machines)

	lazar-HC	lazar-all	RF	LR-sgd	LR-scikit	NN	SVM
Accuracy	85	82	84	79	80	85	82
True positive rate	87	84	81	81	80	85	82
True negative rate	82	80	86	78	80	85	82
Positive predictive value	85	81	85	79	80	85	82
Negative predictive value	85	82	82	80	80	85	82
Nr. predictions	4872	7353	8077	8077	8077	8077	8077

299 Figure 2 depicts the position of all crossvalidation results in receiver operating charac-  
300 teristic (ROC) space.

301 Confusion matrices for all models are available from the git repository [https://git.in-](https://git.in-silico.ch/mutagenicity-paper/tree/crossvalidations/confusion-matrices/)  
302 [silico.ch/mutagenicity-paper/tree/crossvalidations/confusion-matrices/](https://git.in-silico.ch/mutagenicity-paper/tree/crossvalidations/confusion-matrices/), individual pre-  
303 dictions can be found in <https://git.in-silico.ch/mutagenicity-paper/tree/crossvalidations/predictions/>.

304 All investigated algorithm/descriptor combinations give accuracies between (80 and 85%)  
305 which is equivalent to the experimental variability of the *Salmonella typhimurium* mu-  
306 tagenicity bioassay (80-85%, Piegorsch and Zeiger (1991)). Sensitivities and specificities

Figure 2: ROC plot of crossvalidation results (lazar-HC: lazar with high confidence, lazar-all: all lazar predictions, RF: random forests, LR-sgd: logistic regression (stochastic gradient descent), LR-scikit: logistic regression (scikit), NN: neural networks, SVM: support vector machines).

307 are balanced in all of these models.

### 308 **Pyrrrolizidine alkaloid mutagenicity predictions**

309 Mutagenicity predictions of 602 pyrrolizidine alkaloids (PAs) from all investigated  
310 models can be downloaded from [https://git.in-silico.ch/mutagenicity-paper/tree/  
311 pyrrolizidine-alkaloids/pa-predictions.csv](https://git.in-silico.ch/mutagenicity-paper/tree/pyrrolizidine-alkaloids/pa-predictions.csv). A visual representation of all PA predictions  
312 can be found at [https://git.in-silico.ch/mutagenicity-paper/tree/pyrrolizidine-alkaloids/  
313 pa-predictions.pdf](https://git.in-silico.ch/mutagenicity-paper/tree/pyrrolizidine-alkaloids/pa-predictions.pdf).

314 For the visualisation of the position of pyrrolizidine alkaloids in respect to the train-  
315 ing data set we have applied t-distributed stochastic neighbor embedding (t-SNE,  
316 Maaten and Hinton (2008)) for MolPrint2D and CDK descriptors. t-SNE maps  
317 each high-dimensional object (chemical) to a two-dimensional point, maintaining the  
318 high-dimensional distances of the objects. Similar objects are represented by nearby  
319 points and dissimilar objects are represented by distant points. t-SNE coordinates were  
320 calculated with the R `Rtsne` package using the default settings (perplexity = 30, theta  
321 = 0.5, max\_iter = 1000).

322 Figure 3 shows the t-SNE of pyrrolizidine alkaloids (PA) and the mutagenicity train-  
323 ing data in MP2D space (Tanimoto/Jaccard similarity), which resembles basically the  
324 structural diversity of the investigated compounds.

325 Figure 4 shows the t-SNE of pyrrolizidine alkaloids (PA) and the mutagenicity train-  
326 ing data in CDK space (Euclidean similarity), which resembles basically the physical-  
327 chemical properties of the investigated compounds.

328 Figure 5 and Figure 6 depict two example pyrrolizidine alkaloid mutagenicity predictions  
329 in the context of training data. t-SNE visualisations of all investigated models can be  
330 downloaded from <https://git.in-silico.ch/mutagenicity-paper/figures>.

Figure 3: t-SNE visualisation of mutagenicity training data and pyrrolizidine alkaloids (PA) in MP2D space

Figure 4: t-SNE visualisation of mutagenicity training data and pyrrolizidine alkaloids (PA) in CDK space

Figure 5: t-SNE visualisation of MP2D random forest predictions

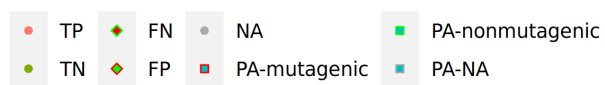

Figure 6: t-SNE visualisation of all CDK lazarus predictions

331 Table 3 summarises the outcome of pyrrolizidine alkaloid predictions from all models  
332 with MolPrint2D and CDK descriptors.

Table 3: Summary of pyrrolizidine alkaloid predictions

Model	MP2D Mutagenic	Nr. predictions	CDK Mutagenic	Nr. predictions
lazar-all	20% (111)	93% (560)	39% (193)	83% (500)
lazar-HC	25% (76)	50% (301)	45% (111)	41% (246)
RF	5% (28)	100% (602)	2% (10)	100% (602)
LR-sgd	21% (127)	100% (602)	16% (97)	100% (602)
LR-scikit	20% (118)	100% (602)	15% (88)	100% (602)
NN	21% (124)	100% (602)	25% (150)	100% (602)
SVM	14% (82)	100% (602)	3% (19)	100% (602)

333 Figure 7 displays the proportion of positive mutagenicity predictions from all models  
334 for the different pyrrolizidine alkaloid groups. Tensorflow models predicted all 602  
335 pyrrolizidine alkaloids, **lazar** MP2D models predicted 560 compounds (301 with high  
336 confidence) and **lazar** CDK models 500 compounds (246 with high confidence).

337 For the **lazar**-HC model, only 50/41% of the PA dataset were within the stricter similarity  
338 thresholds of 0.5/0.9 (MP2D/CDK). Reduction of the similarity threshold to 0.2/0.5 in  
339 the **lazar**-all model increased the amount of predictable PAs to 93/83%. As the other  
340 ML models do not consider applicability domains, all PAs were predicted.

341 Although most of the models show similar accuracies, sensitivities and specificities in  
342 crossvalidation experiments some of the models (MPD-RF, CDK-RF and CDK-SVM)  
343 predict a lower number of mutagens (2-5%) than the majority of the models (14-25%,  
344 Table 3, Figure 7).

345 Over all models, the mean value of mutagenic predicted PAs was highest for otonecines

Figure 7: Summary of pyrrolizidine alkaloid predictions

346 (65%, 407/623), followed by macrocyclic diesters (31%, 1042/3356), dehydropy-  
347 rrolizidines (27%, 74/268), tertiary PAs (19%, 1201/6307) and retronecines (15%,  
348 762/5054).

349 When excluding the aforementioned three deviating models, the rank order stays the  
350 same, but the percentage of mutagenic PAs is higher.

351 The following rank order for mutagenic probability can be deduced from the results of  
352 all models taken together:

353 Necine base: Platynecine < Retronecine « Otonecine

354 Necic acid: Monoester < Diester « Macrocyclic diester

355 Modification of necine base: N-oxide < Tertiary PA < Dehydropyrrolizidine

## 356 Discussion

### 357 Data

358 A new training dataset for *Salmonella* mutagenicity was created from three different  
359 sources (Kazius, McGuire, and Bursi (2005), Hansen et al. (2009), EFSA (2016)). It  
360 contains 8290 unique chemical structures, which is according to our knowledge the  
361 largest public mutagenicity dataset presently available. The new training data can  
362 be downloaded from [https://git.in-silico.ch/mutagenicity-paper/tree/mutagenicity/](https://git.in-silico.ch/mutagenicity-paper/tree/mutagenicity/mutagenicity.csv)  
363 [mutagenicity.csv](https://git.in-silico.ch/mutagenicity-paper/tree/mutagenicity/mutagenicity.csv).

### 364 Algorithms

365 **lazar** is formally a *k-nearest-neighbor* algorithm that searches for similar structures  
366 for a given compound and calculates the prediction based on the experimental data for  
367 these structures. The QSAR literature calls such models frequently *local models*, because

368 models are generated specifically for each query compound. The investigated tensorflow  
369 models are in contrast *global models*, i.e. a single model is used to make predictions for  
370 all compounds. It has been postulated in the past, that local models are more accurate,  
371 because they can account better for mechanisms that affect only a subset of the training  
372 data.

373 Table 1, Table 2 and Figure 2 show that the crossvalidation accuracies of all models are  
374 comparable to the experimental variability of the *Salmonella typhimurium* mutagenicity  
375 bioassay (80-85% according to Piegorsch and Zeiger (1991)). All of these models have  
376 balanced sensitivity (true positive rate) and specificity (true negative rate) and provide  
377 highly significant concordance with experimental data (as determined by McNemar’s  
378 Test). This is a clear indication that *in silico* predictions can be as reliable as the  
379 bioassays. Given that the variability of experimental data is similar to model variability  
380 it is impossible to decide which model gives the most accurate predictions, as models  
381 with higher accuracies might just approximate experimental errors better than more  
382 robust models.

383 Our results do not support the assumption that local models are superior to global  
384 models for classification purposes. For regression models (lowest observed effect level)  
385 we have found however that local models may outperform global models (Helma et al.  
386 (2018)) with accuracies similar to experimental variability.

387 As all investigated algorithms give similar accuracies the selection will depend more on  
388 practical considerations than on intrinsic properties. Nearest neighbor algorithms like  
389 **lazar** have the practical advantage that the rationales for individual predictions can  
390 be presented in a straightforward manner that is understandable without a background  
391 in statistics or machine learning (a screenshot of the mutagenicity prediction for 12,21-  
392 Dihydroxy-4-methyl-4,8-secosenecininan-8,11,16-trione is depicted in Figure 8). This  
393 allows a critical examination of individual predictions and prevents blind trust in models

394 that are intransparent to users with a toxicological background.

## 395 **Descriptors**

396 This study uses two types of descriptors for the characterisation of chemical structures:  
397 *MolPrint2D* fingerprints (MP2D, Bender et al. (2004)) use atom environments (i.e.  
398 connected atom types for all atoms in a molecule) as molecular representation, which  
399 resembles basically the chemical concept of functional groups. MP2D descriptors are  
400 used to determine chemical similarities in the default `lazar` settings, and previous ex-  
401 periments have shown, that they give more accurate results than predefined fingerprints  
402 (e.g. MACCS, FP2-4).

403 *Chemistry Development Kit* (CDK, Willighagen, Mayfield, and Alvarsson (2017)) descrip-  
404 tors were calculated with the PaDEL graphical interface (Yap (2011)). They include 1D  
405 and 2D topological descriptors as well as physical-chemical properties.

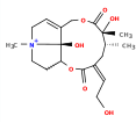

406 All investigated algorithms obtained models within the experimental variability for both  
407 types of descriptors (Table 1, Table 2, Figure 2).

408 Given that similar predictive accuracies are obtainable from both types of descriptors  
409 the choice depends once more on practical considerations:

410 MolPrint2D fragments can be calculated very efficiently for every well defined chem-  
411 ical structure with OpenBabel (O’Boyle et al. (2011)). CDK descriptor calculations  
412 are in contrast much more resource intensive and may fail for a significant number of  
413 compounds ( from 8290).

414 MolPrint2D fragments are generated dynamically from chemical structures and can be  
415 used to determine if a compound contains structural features that are absent in training  
416 data. This feature can be used to determine applicability domains. CDK descriptors  
417 contain in contrast a predefined set of descriptors with unknown toxicological relevance.

**Prediction:**

OC=C1C[C@@H][C](C)[C@@](C)(O)C(=O)OCC2=CC[N+](C@)2[C@H](OC1=O)CC3O)C

Figure 8: lazar screenshot of 12,21-Dihydroxy-4-methyl-4,8-secosenecinonan-8,11,16-trione mutagenicity prediction

418 MolPrint2D fingerprints can be represented very efficiently as sets of features that are  
419 present in a given compound which makes similarity calculations very efficient. Due to  
420 the large number of substructures present in training compounds, they lead however to  
421 large and sparsely populated datasets, if they have to be expanded to a binary matrix  
422 (e.g. as input for tensorflow models). CDK descriptors contain in contrast in every case  
423 matrices with 1442 columns which can cause substantial computational overhead.

## 424 **Pyrrrolizidine alkaloid mutagenicity predictions**

### 425 **Algorithms and descriptors**

426 Figure 7 shows a clear differentiation between the different pyrrrolizidine alkaloid groups.  
427 Nevertheless differences between predictions from different algorithms and descriptors  
428 (Table 3) were not expected based on crossvalidation results.

429 In order to investigate, if any of the investigated models show systematic errors in the  
430 vicinity of pyrrrolizidine-alkaloids we have performed a detailed t-SNE analysis of all  
431 models (see Figure 5 and Figure 6 for two examples, all visualisations can be found at  
432 <https://git.in-silico.ch/mutagenicity-paper/tree/figures>).

433 None of the models showed obvious deviations from their expected behaviour, so the  
434 reason for the disagreement between some of the models remains unclear at the moment.  
435 It is however possible that some systematic errors are covered up by converting high  
436 dimensional spaces to two coordinates and are thus invisible in t-SNE visualisations.

437 Only two compounds from the PA dataset (Senecivernine and Retronecine) are part of  
438 the training set. Both are non-mutagenic and were predicted as non-mutagenic by all  
439 models (instances have been removed from the training set for unbiased predictions).  
440 Despite the exact concordance, we cannot draw any general conclusions about model  
441 performance based on two examples with a single outcome.

#### 442 **Necic acid**

443 The rank order of the necic acid is comparable in all models. PAs from the monoester  
444 type had the lowest genotoxic probability, followed by PAs from the open-ring diester  
445 type. PAs with macrocyclic diesters had the highest genotoxic probability. The result  
446 fits well with current state of knowledge: in general, PAs, which have a macrocyclic  
447 diesters as necic acid, are considered to be more mutagenic than those with an open-ring  
448 diester or monoester (EFSA (2011), Fu et al. (2004)). As pointed out above, open  
449 diesters and macrocyclic PAs have a reduced detoxification due to steric hinderance of  
450 the respective esterases (Ruan et al. (2014)). This was also confirmed by more recent  
451 studies, confirming that macrocyclic- and open-diester are more genotoxic *in vitro* than  
452 monoesters (Hadi et al. (2021); Allemang et al. (2018), Louisse et al. (2019)).

#### 453 **Necine base**

454 In the rank order of necine base PAs, platynecine is the least mutagenic, followed by  
455 retronecine, and otonecine. Saturated PAs of the platynecine-type are generally accepted  
456 to be less or non-mutagenic and have been shown in *in vitro* experiments to form no  
457 DNA-adducts (Xia et al. (2013)). In literature, otonecine-type PAs were shown to be  
458 more mutagenic than those of the retronecine-type (Li et al. (2013)).

#### 459 **Modifications of necine base**

460 The group-specific results reflect the expected relationship between the groups: the  
461 low mutagenic probability of *N*-oxides and the high probability of dehydropyrrolizidines  
462 (DHP) (Chen, Mei, and Fu (2010)). However, *N*-oxides may be *in vivo* converted back  
463 to their parent mutagenic/tumorigenic parent PA (Yan et al. (2008)), on the other  
464 hand they are highly water soluble and generally considered as detoxification products,  
465 which are *in vivo* quickly renally eliminated (Chen, Mei, and Fu (2010)).

466 DHP are regarded as the toxic principle in the metabolism of PAs, and are known to  
467 produce protein- and DNA-adducts (Chen, Mei, and Fu (2010)). None of our investigated  
468 models did meet this expectation and all of them predicted the majority of DHP as non-  
469 mutagenic. However, the following issues need to be considered. On the one hand, all  
470 DHP were outside of the stricter applicability domain of MP2D `lazar`. This indicates  
471 that they are structurally very different than the training data and might be out of the  
472 applicability domain of all models based on this training set. In addition, DHP has two  
473 unsaturated double bounds in its necine base, making it highly reactive. DHP and other  
474 comparable molecules have a very short lifespan *in vivo*, and usually cannot be used in  
475 *in vitro* experiments.

476 Overall the low number of positive mutagenicity predictions was unexpected. PAs are  
477 generally considered to be genotoxic, and the mode of action is also known. Therefore,  
478 the fact that some models predict the majority of PAs as not mutagenic seems contradic-  
479 tory. To understand this result, the experimental basis of the training dataset has to be  
480 considered. The training dataset is based on the *Salmonella typhimurium* mutagenicity  
481 bioassay (Ames test). There are some studies, which show mutagenicity of PAs in the  
482 Ames test (Chen, Mei, and Fu (2010)). Also, Rubiolo et al. (1992) examined several  
483 different PAs and several different extracts of PA-containing plants in the Ames test.  
484 They found that the Ames test was indeed able to detect mutagenicity of PAs, but in  
485 general, appeared to have a low sensitivity. The pre-incubation phase for metabolic  
486 activation of PAs by microsomal enzymes was the sensitivity-limiting step. This could  
487 very well mean that the low sensitivity of the Ames test for PAs is also reflected in the  
488 investigated models.

489 In summary, we found marked differences in the predicted genotoxic probability between  
490 the PA groups: most mutagenic appeared the otonecines and macrocyclic diesters, least  
491 mutagenic the platynecines and the mono- and diesters. These results are comparable

492 with *in vitro* measurements in hepatic HepaRG cells (Louisse et al. (2019)), where  
493 relative potencies (RP) were determined: for otonecines and cyclic diesters  $RP = 1$ , for  
494 open diesters  $RP = 0.1$  and for monoesters  $RP = 0.01$ .

495 Due to a lack of differential data, European authorities based their risk assessment in  
496 a worst-case approach on lasiocarpine, for which sufficient data on genotoxicity and  
497 carcinogenicity were available (HMPC (2014), EMA (2020)). Our data further support  
498 a tiered risk assessment based on *in silico* and experimental data on the relative potency  
499 of individual PAs as already suggested by other authors (Merz and Schrenk (2016), Rutz  
500 et al. (2020), Louisse et al. (2019)).

501 The practical question how to choose model predictions in the absence of experimental  
502 data remains open. Tensorflow predictions do not include applicability domain estima-  
503 tions and the rationales for predictions cannot be traced by toxicologists. Transparent  
504 models like `lazar` may have an advantage in this context, because they present ratio-  
505 nales for predictions (similar compounds with experimental data) which can be accepted  
506 or rejected by toxicologists and provide validated applicability domain estimations.

## 507 **Conclusions**

508 A new public *Salmonella* mutagenicity training dataset with 8309 experimental results  
509 was created and used to train `lazar` and Tensorflow models with MolPrint2D and CDK  
510 descriptors. All investigated algorithm and descriptor combinations showed accuracies  
511 comparable to the interlaboratory variability of the Ames test.

512 Pyrrolizidine alkaloid predictions showed a clear separation between different classes of  
513 PAs which were generally in accordance with the current toxicological knowledge about  
514 these compounds. Some of the models showed however a substantially lower number of  
515 mutagenicity predictions, despite similar crossvalidation results and we were unable to

516 identify the reasons for this discrepancy within this investigation.

517 Our data show that large difference exist with regard to mutagenic probabilities between  
518 different pyrrolizidine subgroups. To adjust risk assessment of pyrrolizidine contami-  
519 nation, our data supports a tiered risk assessment based on *in silico* predictions and  
520 experimental data of individual pyrrolizidine alkaloids.
